

In our HomeSense program, we have classified the readings as High or Critical as follows,

If the device's energy consumption is within the normal range, then the device is in normal condition.

Our team has decided that if a device's energy consumption is **up to** 50% higher than the maximum value in the normal range for the respective device, then the reading is determined to be “High”. If the device's energy consumption exceeds the maximum normal value by **more than** 50%, the reading is termed “Critical”.

We chose this range because standard operational spikes such as heavy usage, temperature changes, and start-up loads can cause swings in a device’s consumption of energy. Allocating a 50% maximum value allows room for definite concerns and prevents frequent false positive readings.
